

INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

ESTABLISHMENT OF NETWORK CONNECTIONS

The present invention relates to the establishment of network connections, such as for example, the establishment of a connection from a client computing entity ("client")
 5 to a server computing entity ("server"), and thus, *inter alia*, to the establishment of such connections as may occur during browsing at the client of a website which is hosted on the server.

Typically when a client connects to a server on which a website is hosted, the client
 10 will initially download a copy of a page from the website, which has a number of links to other pages. These other pages may be part of the same site or a different site. These links are effectively pointers to the other pages which are actuable to cause connection to those pages; traditionally downloading of one of these other pages to the client is also instigated upon actuation of the relevant link. This can result in
 15 undesirable delay in obtaining these pages. One aspect of the present invention provides a method of establishing network connections which ameliorates this situation.

According to a first aspect of the present invention there is provided a method of
 20 browsing a website which has a first web page with at least second and third links to second and third web pages respectively, the method including the steps of: subsequent to downloading the first web page, but prior to actuation of either the second or third links, commencing the process of downloading the second and third web pages; wherein
 25 the process of downloading the second and third web pages is performed on the basis of a predetermined relative priority.

By commencing downloading of the second and third pages pre-emptively, i.e. prior to actuation of the links to those pages by a user, the pages will be available for
 30 browsing more quickly upon actuation of the links by a user, typically because they will be accessed from cache memory of the client – the location to which they are preferably downloaded. The relative priority of the download broadly speaking determines the relative time taken, as measured from acquisition of the second and third links by the client, for the corresponding pages to be downloaded. Accordingly,

in one embodiment the second and third pages are downloaded simultaneously, and the relative priority determines the relative speeds at which they are downloaded. In a further embodiment the second and third pages are downloaded one after the other, i.e. only when the process of downloading one of the second and third pages is complete does the process of downloading the other start, with the relative priority simply determining the order of the download.

Relative priority may be determined for example in accordance with the relative probability of the respective links being actuated (this being established for example on the basis of the relative numbers of previous browser connections which have requested to each of these pages from the first web page), so that the likelihood is that pages used most often will be downloaded most rapidly. Alternatively the priorities may reflect economic concerns, so that more profitable pages are downloaded more quickly.

In one embodiment, the download speed of the pages is controlled by the client. Typically, the downloaded pages will be held within an ephemeral cache memory of the client, usually known as "session cache" because it may be persistent only for the duration of a browsing session.

Embodiments of the invention will now be described, by way of example, and with reference to the accompanying drawings, in which:

Figs. 1 to 3 are schematic illustrations of the process of connecting a client to a server and downloading plural web pages according to an embodiment of the present invention;

Fig. 4 is an example of html code for a page having links in accordance with an embodiment of the present invention;

Fig. 5 is a schematic illustration of one process of downloading a web page in which the speed of download is controlled primarily by the client; and

Fig. 6 is further schematic illustration of the process of Fig. 5.

Referring now to Fig. 1, a network, in this example the Internet, is illustrated schematically, and includes a client computer 10, a server computer 20, and a Domain Name Service ("DNS") server 30, which converts or "resolves" URLs in alphanumeric characters (e.g. <http://www.bbc.co.uk>) into numeric Internet Protocol ("IP") addresses (e.g. 192.168.56.3 – this being an exemplary IP address and not the IP address associated with the aforementioned URL), which are then used to establish contact with the intended network destination. In the present example the browser programme within the client 10 is operating to request download of a web page with the fictitious (at the time of writing) URL <http://www.safari.fun.co.uk>. This is resolved to an IP address at the DNS server 30 and passed on to the server 20 where the desired web page is hosted. Referring now to Fig. 2, upon receipt of the request for the web page 100, the server 20 returns a copy of the page to the client 10, which as can be seen from Fig. 2, includes two pointers to other pages: "wildlife" and "hunting", 102 and 104 respectively. Each of these pointers is actuatable to connect to the location within the network to which they point (in this example a different page of the same website), and they are therefore known as "links" to those pages.

Referring now to Fig. 3, in accordance with the present invention, upon receiving the page 100, the browser programme of the client scans the html code for the page 100 for the purpose of detecting any links, and upon detection of such links, automatically (i.e. without the user of the client actuating the links) requests the pages to which the links point from the server 30, this action being illustrated schematically in Fig. 3.

Referring additionally to Fig. 4, the code for the page includes the two links 102, 104 in text form, as part of what is known as the "markup" for the page as a whole (i.e. text and other material in conjunction with the labels in html which provide, *inter alia*, format instructions). In accordance with the present embodiment of the invention, each of the links has associated with it a priority which denotes the relative speed with which it is to be downloaded from the server. The priority for the links 102, 104 is "pri=1" for the wildlife link 102 and "pri=5" for the hunting link, and this is effectively an instruction to download the hunting link 104 five times more quickly than the Wildlife link 102. According to one embodiment the priority is based on the probability that it will be actuated by a user subsequent to downloading by a user of the page on which the links are located, so that the relative priorities of the two links reflect the fact that, for example, the wildlife page to which link 102 points is five

times less likely to be the next destination than the hunting page to which link 104 points. Typically these probabilities are calculated using the relative numbers of previous occasions on which each of the two links 102 and 104 are actuated. It is equally possible however that the priority may be based on some other premise. For example, the priority for the relative speed for pre-emptive download of two or more pages may equally be based upon the revenue or margin generated from those pages, so that for example where there are two links, and one is twice as profitable as another, the most profitable link may be given a priority rating twice (for example) the size of the less profitable link to reflect this, so that it is pre-emptively downloaded twice as fast. The downloaded pages are stored in the cache memory within the client and if corresponding links are actuated, are retrieved from the cache memory (a process significantly faster than downloading a page).

One way in which the download speed of a page from a server to a client may be controlled from the client side will now be illustrated in highly schematic form, using for the purposes of exemplification Transmission Control Protocol over Internet Protocol ("TCP/IP"), of which hypertext transfer protocol ("http") is a client-server specific form. Referring now to Fig. 5, when a server receives a request for a web page, for example, components of the page, such as text with hyper text markup language ("html") labels, or pictures pass down through the hierarchy of systems programmes (sometimes known as the "stack") within the server, to the TCP/IP programme (or "layer"). The TCP/IP layer operates to divide the component in question into packets E which are then transmitted to the client. The TCP/IP layer operates on the basis of time windows, and dispatches as many packets E_1, E_2, \dots, E_n to the client as possible over the course of a time window T_w , the number of packets which may be dispatched in a given time window being neither determinate in advance, nor necessarily consistent from one time window to the next (since it may be influenced by such things as the load on the server, for example). Having dispatched the packets, the TCP/IP layer then awaits acknowledgement from the client before dispatching any further packets in a subsequent time window, and it is by controlling the speed of acknowledgement from the client that the download speed may be controlled from the client side (the relatively indeterminate nature of the time elapsed between receipt by the client of a bundle of packets from the server, and the dispatch of an acknowledgement by the client being illustrated schematically by the dotted

timeline on the client side). Specifically the client allocates a proportion of its processor time to the processing of a given http request on the basis of the priority marked in the link, which as can be seen from Fig. 3 is specified by the parameter "P" (in the illustrated example Pri 1 and Pri 5 for the wildlife and hunting pages respectively), and is therefore only able to issue acknowledgements to packets dispatched from the server 20 within this allocated proportion of its processing time. The relative speed with which the wildlife and hunting pages are downloaded is therefore, in the present example, controlled by the differing response times in issuing acknowledgements in respect of the requests for the wildlife and hunting pages.

10

Referring now to Fig. 6, each http request involves the launching of one, and usually more small programmes within the browser of the client, known as a "thread", which sets up a connection to the server for the retrieval of a particular component of the requested web page, and performs functions such as the acknowledgement of receipt of packets from the server described above. For example, upon requesting downloading of a web page an initial thread is launched to retrieve the most rapid component of the page to be downloaded, i.e. any text and embedded html labels within the text. This html "document" will also contain an indication of other elements within the page, such as, for example pictures stored as .jpg (an abbreviation for "joint photographic experts group") files. Once the browser detects that the requested page also contains a .jpg file it will launch a further thread to retrieve the .jpg file. Fig. 6 shows schematically the retrieval from storage of each of these .jpg files, their passage through the hierarchy of systems programmes until they reach the TCP/IP layer, and their dispatch as packets E to the client.

25

In a further modification, the use of relative priority ratings for the downloading of pages pointed to from links can be applied to the acquisition of elements of the content from those pages, such as images for example. Thus it may be desirable that some elements of content, such as one or more particular images for example, are more rapidly acquired by the client than others, for example because their acquisition is deemed to be financially more advantageous, or because it has been determined that the particular image is the one that is most sought after of all those on the page in question. These elements of content may therefore have priorities associated with them which, for example instruct the client as to the relative speed with which the

30

thread retrieving the content element is processed by the client. The use of relative priorities to process download of content elements may be employed either when nested within priorities for the download of the page on which the content element is situated, or independently.

5

An alternative manner of providing a priority based pre-emptive download of pages from links on a source page involves simply the serial downloading of pages, on the basis of relative priority. Thus for example the wildlife page may in the link be denoted as having "order=1", and the hunting page "order=2". Links including such instructions will then be processed to download the wildlife page first in its entirety, and then the hunting page. This technique may equally be applied to the downloading of content elements.

In all the above-described examples, pre-emptive downloading of pages may be superseded by the manual intervention of a user, for example by actuating a link, or otherwise requesting a page (whether a page which is in the process of being pre-emptively downloaded or not). In one example any manual intervention causes the processing of http requests for all pages which are not requested by the manual intervention to stop. The content downloaded up to that point may then, if desired, be retrieved from cache memory and augmented with the remaining content on the server. It is to be understood that in the embodiment in which pages are downloaded pre-emptively one after the other (as opposed to simultaneously at different speeds), pre-emptive downloading of both pages is considered to have started with the commencement of the http request for the first of these pages to be pre-emptively downloaded, since the process requires that first page to be downloaded completely prior to commencing an http request for the second of these two pages; thus it is to be regarded as a single pre-emptive downloading process involving two (or more as the case may be) separate pages.

Preferably, each of the links on the homepage is actually an alias for one or more URLs which identify specific secondary servers on which the pages accessible via the links on the home page are hosted. In this way a connection may be made more rapidly to the secondary server, rather than requests being re-routed from the server hosting the home page. This is described more fully in our co-pending UK patent

application GB 0217795.4.

CLAIMS

1. A method of browsing a website which has a first web page with at least second and third links to second and third web pages respectively, the method including the steps of:
subsequent to downloading the first web page, but prior to actuation of either the second or third links, commencing the process of downloading the second and third web pages; wherein
the process of downloading the second and third web pages is performed on the basis of a predetermined relative priority.
2. A method according to claim 1 wherein the predetermined relative priority provides predetermined relative download speeds for the second and third pages.
3. A method according to claim 2 wherein the download of the second and third pages takes place simultaneously, the relative speeds corresponding to their relative priority.
4. A method according to claim 1 wherein the predetermined relative priority provides a predetermined order for downloading the second and third pages.
5. A method according to claim 4 wherein the download of one of the second and third pages only commences when download of the other of the second and third pages is complete.
6. A method according to claim 1 further comprising the step of downloading elements of content of the second and third pages on the basis of a predetermined priority.
7. A method according to claim 1 further comprising the step of storing the second and third web pages in cache memory within the client.
8. A method according to claim 1 wherein the speed of downloading is controlled by at least the client.

9. A method according to claim 8 wherein the relative speed of downloading of the second and third pages is controlled on the basis of instructions within the second and third links.

5

10. A method according to claim 1 wherein the first, second and third pages are all on the same website.

11. A method according to claim 1 wherein each of the links has a specific URL
10 which identifies uniquely the address within the network of a server on which the second and/or third pages are hosted.

ESTABLISHMENT OF NETWORK CONNECTIONS

ABSTRACT

- 5 Upon downloading of a home page for example, which contains two or more links to
other pages (either within the same site, or part of a different site), the links to those
pages are pre-emptively actuated, i.e. before manual actuation by a user.
Consequential download of these pages may be either performed simultaneously but
at different speeds, thereby reflecting pre-determined weightings for each of the
10 pages, or one after the other, with the order reflecting the weightings.

ESTABLISHMENT OF NETWORK CONNECTIONS

The present invention relates to the establishment of network connections, such as for example, the establishment of a connection from a client computing entity ("client")
 5 to a server computing entity ("server"), and thus, *inter alia*, to the establishment of such connections as may occur during browsing at the client of a website which is hosted on the server.

Typically when a client connects to a server on which a website is hosted, the client
 10 will initially download a copy of a page from the website, which has a number of links to other pages. These other pages may be part of the same site or a different site. These links are effectively pointers to the other pages which are actuable to cause connection to those pages; traditionally downloading of one of these other pages to the client is also instigated upon actuation of the relevant link. This can result in
 15 undesirable delay in obtaining these pages. One aspect of the present invention provides a method of establishing network connections which ameliorates this situation.

According to a first aspect of the present invention there is provided a method of
 20 browsing a website which has a first web page with at least second and third links to second and third web pages respectively, the method including the steps of: subsequent to downloading the first web page, but prior to actuation of either the second or third links, commencing the process of downloading the second and third web pages; wherein
 25 the process of downloading the second and third web pages is performed on the basis of a predetermined relative priority.

By commencing downloading of the second and third pages pre-emptively, i.e. prior to actuation of the links to those pages by a user, the pages will be available for
 30 browsing more quickly upon actuation of the links by a user, typically because they will be accessed from cache memory of the client – the location to which they are preferably downloaded. The relative priority of the download broadly speaking determines the relative time taken, as measured from acquisition of the second and third links by the client, for the corresponding pages to be downloaded. Accordingly,

in one embodiment the second and third pages are downloaded simultaneously, and the relative priority determines the relative speeds at which they are downloaded. In a further embodiment the second and third pages are downloaded one after the other, i.e. only when the process of downloading one of the second and third pages is complete does the process of downloading the other start, with the relative priority simply determining the order of the download.

Relative priority may be determined for example in accordance with the relative probability of the respective links being actuated (this being established for example on the basis of the relative numbers of previous browser connections which have requested to each of these pages from the first web page), so that the likelihood is that pages used most often will be downloaded most rapidly. Alternatively the priorities may reflect economic concerns, so that more profitable pages are downloaded more quickly.

In one embodiment, the download speed of the pages is controlled by the client. Typically, the downloaded pages will be held within an ephemeral cache memory of the client, usually known as "session cache" because it may be persistent only for the duration of a browsing session.

Embodiments of the invention will now be described, by way of example, and with reference to the accompanying drawings, in which:

Figs. 1 to 3 are schematic illustrations of the process of connecting a client to a server and downloading plural web pages according to an embodiment of the present invention;

Fig. 4 is an example of html code for a page having links in accordance with an embodiment of the present invention;

Fig. 5 is a schematic illustration of one process of downloading a web page in which the speed of download is controlled primarily by the client; and

Fig. 6 is further schematic illustration of the process of Fig. 5.

Referring now to Fig. 1, a network, in this example the Internet, is illustrated schematically, and includes a client computer 10, a server computer 20, and a Domain Name Service ("DNS") server 30, which converts or "resolves" URLs in alphanumeric characters (e.g. <http://www.bbc.co.uk>) into numeric Internet Protocol ("IP") addresses (e.g. 192.168.56.3 – this being an exemplary IP address and not the IP address associated with the aforementioned URL), which are then used to establish contact with the intended network destination. In the present example the browser programme within the client 10 is operating to request download of a web page with the fictitious (at the time of writing) URL <http://www.safari.fun.co.uk> . This is resolved to an IP address at the DNS server 30 and passed on to the server 20 where the desired web page is hosted. Referring now to Fig. 2, upon receipt of the request for the web page 100, the server 20 returns a copy of the page to the client 10, which as can be seen from Fig. 2, includes two pointers to other pages: "wildlife" and "hunting", 102 and 104 respectively. Each of these pointers is actuatable to connect to the location within the network to which they point (in this example a different page of the same website), and they are therefore known as "links" to those pages.

Referring now to Fig. 3, in accordance with the present invention, upon receiving the page 100, the browser programme of the client scans the html code for the page 100 for the purpose of detecting any links, and upon detection of such links, automatically (i.e. without the user of the client actuating the links) requests the pages to which the links point from the server 30, this action being illustrated schematically in Fig. 3.

Referring additionally to Fig. 4, the code for the page includes the two links 102, 104 in text form, as part of what is known as the "markup" for the page as a whole (i.e. text and other material in conjunction with the labels in html which provide, *inter alia*, format instructions). In accordance with the present embodiment of the invention, each of the links has associated with it a priority which denotes the relative speed with which it is to be downloaded from the server. The priority for the links 102, 104 is "pri=1" for the wildlife link 102 and "pri=5" for the hunting link, and this is effectively an instruction to download the hunting link 104 five times more quickly than the Wildlife link 102. According to one embodiment the priority is based on the probability that it will be actuated by a user subsequent to downloading by a user of the page on which the links are located, so that the relative priorities of the two links reflect the fact that, for example, the wildlife page to which link 102 points is five

times less likely to be the next destination than the hunting page to which link 104 points. Typically these probabilities are calculated using the relative numbers of previous occasions on which each of the two links 102 and 104 are actuated. It is equally possible however that the priority may be based on some other premise. For example, the priority for the relative speed for pre-emptive download of two or more pages may equally be based upon the revenue or margin generated from those pages, so that for example where there are two links, and one is twice as profitable as another, the most profitable link may be given a priority rating twice (for example) the size of the less profitable link to reflect this, so that it is pre-emptively downloaded twice as fast. The downloaded pages are stored in the cache memory within the client and if corresponding links are actuated, are retrieved from the cache memory (a process significantly faster than downloading a page).

One way in which the download speed of a page from a server to a client may be controlled from the client side will now be illustrated in highly schematic form, using for the purposes of exemplification Transmission Control Protocol over Internet Protocol ("TCP/IP"), of which hypertext transfer protocol ("http") is a client-server specific form. Referring now to Fig. 5, when a server receives a request for a web page, for example, components of the page, such as text with hyper text markup language ("html") labels, or pictures pass down through the hierarchy of systems programmes (sometimes known as the "stack") within the server, to the TCP/IP programme (or "layer"). The TCP/IP layer operates to divide the component in question into packets E which are then transmitted to the client. The TCP/IP layer operates on the basis of time windows, and dispatches as many packets E_1, E_2, \dots, E_n to the client as possible over the course of a time window T_w , the number of packets which may be dispatched in a given time window being neither determinate in advance, nor necessarily consistent from one time window to the next (since it may be influenced by such things as the load on the server, for example). Having dispatched the packets, the TCP/IP layer then awaits acknowledgement from the client before dispatching any further packets in a subsequent time window, and it is by controlling the speed of acknowledgement from the client that the download speed may be controlled from the client side (the relatively indeterminate nature of the time elapsed between receipt by the client of a bundle of packets from the server, and the dispatch of an acknowledgement by the client being illustrated schematically by the dotted

timeline on the client side). Specifically the client allocates a proportion of its processor time to the processing of a given http request on the basis of the priority marked in the link, which as can be seen from Fig. 3 is specified by the parameter “P” (in the illustrated example Pri 1 and Pri 5 for the wildlife and hunting pages respectively), and is therefore only able to issue acknowledgements to packets dispatched from the server 20 within this allocated proportion of its processing time. The relative speed with which the wildlife and hunting pages are downloaded is therefore, in the present example, controlled by the differing response times in issuing acknowledgements in respect of the requests for the wildlife and hunting pages.

10

Referring now to Fig. 6, each http request involves the launching of one, and usually more small programmes within the browser of the client, known as a “thread”, which sets up a connection to the server for the retrieval of a particular component of the requested web page, and performs functions such as the acknowledgement of receipt of packets from the server described above. For example, upon requesting downloading of a web page an initial thread is launched to retrieve the most rapid component of the page to be downloaded, i.e. any text and embedded html labels within the text. This html “document” will also contain an indication of other elements within the page, such as, for example pictures stored as .jpg (an abbreviation for “joint photographic experts group”) files. Once the browser detects that the requested page also contains a .jpg file it will launch a further thread to retrieve the .jpg file. Fig. 6 shows schematically the retrieval from storage of each of these .jpg files, their passage through the hierarchy of systems programmes until they reach the TCP/IP layer, and their dispatch as packets E to the client.

25

In a further modification, the use of relative priority ratings for the downloading of pages pointed to from links can be applied to the acquisition of elements of the content from those pages, such as images for example. Thus it may be desirable that some elements of content, such as one or more particular images for example, are more rapidly acquired by the client than others, for example because their acquisition is deemed to be financially more advantageous, or because it has been determined that the particular image is the one that is most sought after of all those on the page in question. These elements of content may therefore have priorities associated with them which, for example instruct the client as to the relative speed with which the

30

thread retrieving the content element is processed by the client. The use of relative priorities to process download of content elements may be employed either when nested within priorities for the download of the page on which the content element is situated, or independently.

5

An alternative manner of providing a priority based pre-emptive download of pages from links on a source page involves simply the serial downloading of pages, on the basis of relative priority. Thus for example the wildlife page may in the link be denoted as having "order=1", and the hunting page "order=2". Links including such
 10 instructions will then be processed to download the wildlife page first in its entirety, and then the hunting page. This technique may equally be applied to the downloading of content elements.

In all the above-described examples, pre-emptive downloading of pages may be
 15 superseded by the manual intervention of a user, for example by actuating a link, or otherwise requesting a page (whether a page which is in the process of being pre-emptively downloaded or not). In one example any manual intervention causes the processing of http requests for all pages which are not requested by the manual intervention to stop. The content downloaded up to that point may then, if desired, be
 20 retrieved from cache memory and augmented with the remaining content on the server. It is to be understood that in the embodiment in which pages are downloaded pre-emptively one after the other (as opposed to simultaneously at different speeds), pre-emptive downloading of both pages is considered to have started with the commencement of the http request for the first of these pages to be pre-emptively
 25 downloaded, since the process requires that first page to be downloaded completely prior to commencing an http request for the second of these two pages; thus it is to be regarded as a single pre-emptive downloading process involving two (or more as the case may be) separate pages.

30 Preferably, each of the links on the homepage is actually an alias for one or more URLs which identify specific secondary servers on which the pages accessible via the links on the home page are hosted. In this way a connection may be made more rapidly to the secondary server, rather than requests being re-routed from the server hosting the home page. This is described more fully in our co-pending UK patent

application GB 0217795.4.

CLAIMS

1. A method of browsing a website which has a first web page with at least second and third links to second and third web pages respectively, the method including the steps of:
 - subsequent to downloading the first web page, but prior to actuation of either the second or third links, commencing the process of downloading the second and third web pages; wherein
 - the process of downloading the second and third web pages is performed on the basis of a predetermined relative priority.
2. A method according to claim 1 wherein the predetermined relative priority provides predetermined relative download speeds for the second and third pages.
3. A method according to claim 2 wherein the download of the second and third pages takes place simultaneously, the relative speeds corresponding to their relative priority.
4. A method according to claim 1 wherein the predetermined relative priority provides a predetermined order for downloading the second and third pages.
5. A method according to claim 4 wherein the download of one of the second and third pages only commences when download of the other of the second and third pages is complete.
6. A method according to claim 1 further comprising the step of downloading elements of content of the second and third pages on the basis of a predetermined priority.
7. A method according to claim 1 further comprising the step of storing the second and third web pages in cache memory within the client.
8. A method according to claim 1 wherein the speed of downloading is controlled by at least the client.

9. A method according to claim 8 wherein the relative speed of downloading of the second and third pages is controlled on the basis of instructions within the second and third links.

5

10. A method according to claim 1 wherein the first, second and third pages are all on the same website.

11. A method according to claim 1 wherein each of the links has a specific URL
10 which identifies uniquely the address within the network of a server on which the second and/or third pages are hosted.

ESTABLISHMENT OF NETWORK CONNECTIONS

ABSTRACT

- 5 Upon downloading of a home page for example, which contains two or more links to other pages (either within the same site, or part of a different site), the links to those pages are pre-emptively actuated, i.e. before manual actuation by a user. Consequential download of these pages may be either performed simultaneously but at different speeds, thereby reflecting pre-determined weightings for each of the
- 10 pages, or one after the other, with the order reflecting the weightings.
